laserdata

Prepared for **Robinhood**

Real-time card state for Robinhood's stand-in authorizer, on LaserData.

Every balance and card-status change reaches **every stand-in replica in milliseconds**, so its decisions match the primary's, even at the market open. It runs on its own broker beside Kafka, so nothing else has to move.

One card account at the open,
as the event log sees it.
Now multiply by every account.

09:30:00.412	account.buy_order	A00412093	spendable $1,312.00 → $72.00
09:30:00.415	standin.cache	A00412093	seq 4182 applied
09:30:00.700	auth.request	A00412093	$86.40, card present
09:30:00.701	stand-in: declined, insufficient funds · same as the primary		

From the creators of APACHE IGGY

15×
faster P99 latency
than Apache Kafka

4×
higher throughput
than Apache Kafka

60–70%
lower infrastructure cost
compute, storage and network

Apache Iggy vs Apache Kafka, LaserData testing. Results vary by workload.

What you shared	**A stand-in card authorizer** on its own stack, caching each account from Kafka, with 2 s to answer the processor. Kafka in every line of the business, 20–50 ms a hop. (Robinhood blog and talks)
Where it fits	**The card state lane:** spendable balance and card status, keyed by account, read by every stand-in replica. Kafka, Confluent and the primary authorizer stay.
Next	**AI agents** that act for customers read the same live account state, with session, context, memory and replay from Laser SDK.
Underneath	**One durable event log.** LaserData, powered by Apache Iggy.

Try it in 15 minutes. Let the numbers decide.

A ready-made kit for Robinhood: **500,000 card accounts**, stand-in replicas, a market-open burst, a settlement backfill and a Kafka shadow bridge. It prints your lane's p99 and stand-in decisions that disagree with the primary, every second.

Open the Robinhood kit and write-up →

Then a 2–4 week evaluation on one mirrored account-update topic, beside Kafka and the primary authorizer. **No advantage, no migration.**
