laserdata

Prepared for **Optiver**

A change log for config and pricing tables at Optiver, on LaserData.

Every committed change lands once, in order per table. **A process that starts or restarts rebuilds its tables from the log** in milliseconds, checked row for row, with no Postgres snapshot. It runs beside PG feed, so nothing else has to move.

One table, one process restart,
as the event log sees it.
Now multiply by thousands of processes.

From the creators of APACHE IGGY

15×
faster P99 latency
than Apache Kafka

4×
higher throughput
than Apache Kafka

60–70%
lower infrastructure cost
compute, storage and network

Apache Iggy vs Apache Kafka, LaserData testing. Results vary by workload.

What you shared	PG feed sends **config and pricing changes to thousands of processes** from one logical decoding path. "Larger tables make the initial snapshot expensive and slow down new subscribers." (Optiver Technology blog)
Where it fits	**The table change log:** committed changes keyed by table, with checkpoints, read by processes that start or restart. Postgres, the write path and PG feed stay.
Next	**AI agents** act on the same log, with session, context, memory and replay from Laser SDK.
Underneath	**One durable event log.** LaserData, powered by Apache Iggy.

Try it in 15 minutes. Let the numbers decide.

A ready-made kit for Optiver: **32 config and pricing tables at 5,000 row changes/s**, subscriber nodes serving 2,000 processes each, storms of 200 processes restarting at once, a state-hash check on every change and a Postgres shadow bridge on a temporary slot. It prints p99 and rejoin time every second.

Open the Optiver kit and write-up →

Then a 2–4 week evaluation on a few mirrored tables, beside PG feed. **No advantage, no migration.**
